Except for fair copying, no part of this publication may be reproduced, stored in a retrieval system, or transmitted, in any form or by any means electronic, mechanical, photocopying, recording or otherwise, without the prior written permission of the Geotechnical Engineering Group.

Papers or other contributions in AAU Geotechnical Engineering Papers and the statements made or opinions expressed therein are published on the understanding that the author of the contribution is solely responsible for the opinions expressed in it and that its publication does not necessarily imply that such statements or opinions are or reflect the views of the AAU Geotechnical Engineering Group.

The AAU Geotechnical Engineering Papers - AGEp - are issued for early dissemination and book keeping of research results from the Geotechnical Engineering Group at Aalborg University (Department of Civil Engineering). Moreover, the papers accommodate proliferation and documentation of field and laboratory test series not directly suited for publication in journals or proceedings.

The papers are numbered ISSN 1398-6465 R<two digit year code><two digit consecutive number>. For internal purposes the papers are, further, submitted with coloured covers in the following series:

Series	Colour
Laboratory testing papers	sand
Field testing papers	grey
Manuals & guides	red
Soil Mechanics papers	blue
Foundation Engineering papers	green
Engineering Geology papers	yellow
Environmental Engineering papers	brown

In general the AGEp papers are submitted to journals, conferences or scientific meetings and hence, whenever possible, reference should be given to the final publication (journal, proceeding etc.) and not to the AGEp paper.

# Pile Driving Fatigue Damage, A Case Story

## Dégâts de Fatigue en Battage de Pieu, un exposé d'un cas concret

J. Lorin Rasmussen & T. Feld  
*RAMBØLL, Copenhagen, Denmark*

Keywords: Driveability, Fatigue, Pile, Concrete Pile, Hammer, Recommendations.

**ABSTRACT:** Concrete piles were driven by a hydraulic hammer for a new heavy loaded building at a refuse disposal plant, located in Copenhagen, Denmark. Some of the piles got fatigue damage during driving. The fatigue damage was due to the fact that the piles were driven with too much energy, and the falling height was too high compared to the total number of blows. The investigation concluded that it was necessary to decrease the falling height of the hammer with increasing total number of blows, or reduce the falling height with increasing driving resistance. Finally recommendations are given for the falling heights of the hammer compared to the total number of blows in order to avoid fatigue damage on concrete piles.

**RÉSUMÉ:** Des pieux en béton étaient battus par un mouton hydraulique pour un nouveau bâtiment fortement chargé à une usine d'incinération, située à Copenhague, Danemark. Quelques-uns des pieux ont eu des dégâts de fatigue en cours du battage. Les dégâts de fatigue résultaient du fait que les pieux étaient battus avec trop d'énergie, et l'hauteur de chute était trop élevée en comparaison du nombre total de coups. L'examen a conclu qu'il était nécessaire de réduire l'hauteur de chute du mouton avec un nombre total de coups augmentant, ou réduire l'hauteur de chute avec une résistance de battage augmentant. Enfin des recommandations ont été données pour les hauteurs de chute comparées au nombre total de coups pour qu'on n'ait pas de dégâts de fatigue aux pieux en béton

## 1 INTRODUCTION

The foundation of a new heavy building consisted of a piled foundation with  $0.4 \times 0.4 \text{ m}^2$  reinforced concrete piles. The piles were driven with a hydraulic 60 kN hammer. Some of the piles got refusal before the target penetration. These piles were driven with a stroke up to 1.0 m. These too high falling heights compared to the total number of blows resulted in pile driving fatigue damage on the piles.

A driveability study on a  $0.4 \times 0.4 \text{ m}^2$  concrete pile was carried out using the GRLWEAP program. This commercial driveability program calculates the stress gap in the individual pile element for each blow, the stresses form the input to the fatigue analysis, carried out as described by NS 3473 Code.

A computer program developed by RAMBØLL was designed to carry out the calculation of the fatigue damage ratio for different pile elements with given stress histories.

## 2 DRIVEABILITY STUDY

### 2.1 Soil Condition

The characteristic soil parameters used in the study are depicted in Figure 1. The upper sand layer (0 - 1.2 m) is fill and the clay and sand layers down to 4 m below the ground level are post glacially deposits. The clay layer from 4 to 9.4 m below ground level is glacial clay till, while the pile tips is placed in a glacial sand layer below 9.4 m.

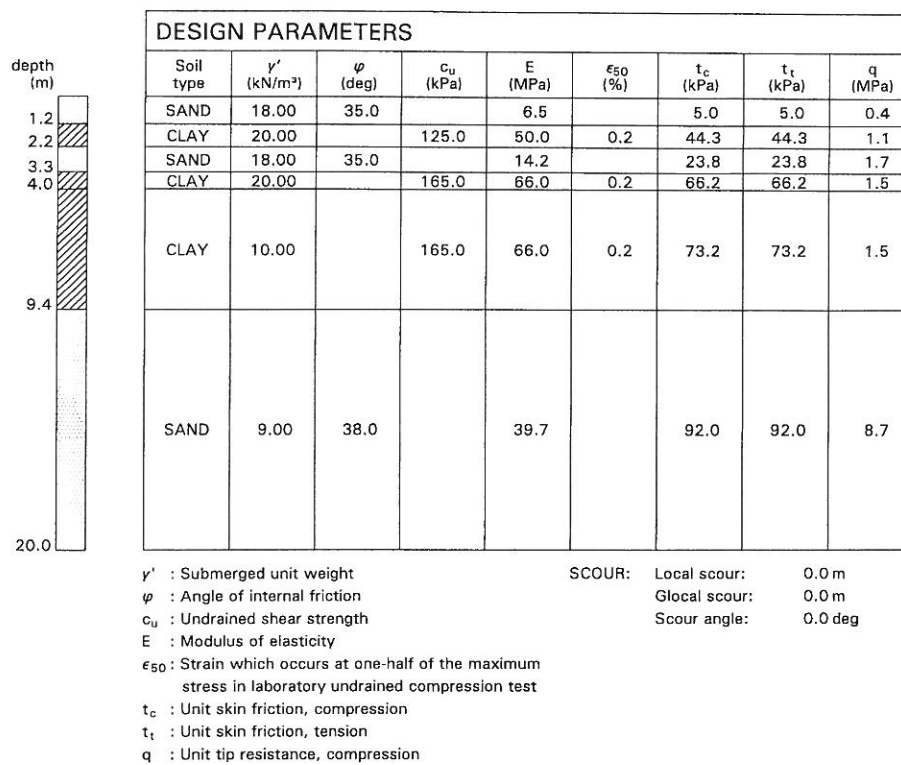

Figure 1. Characteristic Soil Parameters.

The driveability study was carried out using the computer program GRLWEAP. In the analysis the soil parameters in Figure 1 and following dynamic parameters were used:

Table 1 Dynamic Parameters used in Driveability Study

Dynamic Parameters		
Quake		2.5 mm
Damping clay	side	0.65 s/m
Damping clay	side	0.65 s/m
	tip	0.50 s/m
Damping sand	side	0.16 s/m
	tip	0.50 s/m

It was assumed that the dynamic skin friction is equal to the static skin friction times an empirical e-factor taken as 0.7 as an expected value for a hydraulic hammer. The result of the driveability study is given in Figure 2.

The predicted driving resistance was in accordance with the observed driving resistance.

Figure 2. Observed and Predicted Driving Resistance.

## 2.2 Pile Data

The piles were  $0.4 \times 0.4 \text{ m}^2$  prestressed concrete piles with a length of 18 m. The piles were coated on the upper 4 m in order to limit the down drag from the upper post glacial layers.

## 2.3 Pile Driving Equipment

The piles were driven with a 60 kN hydraulic Junttan hammer. The stroke of the hammer during the driving varied from 0.20 m in the beginning to 1.0 m at the last 2.5 m of the driving of pile no 107, and from 0.2 m to 0.80 -1.0 m at the last 5 m for pile 109.

## 3 PILE DRIVING FATIGUE ANALYSIS

The pile driving induced partial fatigue damage was calculated using the following procedure: Each pile was divided into a number of elements during the driveability analysis. Output from the computer program, GRLWEAP can be ordered to specify maximum and minimum stress for each element at each depth analyzed, following the stress gap was calculated from these stresses.

For each element the fatigue damage was calculated in accordance with Palmgren-Miner's equation for each driving depth as:

$$\eta = \sum_{i=1}^{i=n} \frac{n_i}{N_i}$$

where  $\eta$  = the partial damage;  $n_i$  = number of blows for a given stress gap; and  $N_i$  = the number of blows for fatigue damage.

$N$  can be calculated in accordance with the following equation proposed by Aas-Jacobsen (1970). When this equation is unity, fatigue damage will occur.

$$\left( \frac{\sigma_{\max}}{f_c} \right) + 0.064 \cdot \left( 1 - \frac{\sigma_{\min}}{\sigma_{\max}} \right) \cdot \log N = 1$$

where  $\sigma_{\max}$  = the maximum compression stress;  $\sigma_{\min}$  = the maximum tension stress;  $f_c$  = the concrete reference stress, taken as 15.6 MPa; and  $N$  = number of blows.

In Table 2 the partial fatigue damage is given. At a driving depth of 15 meter the fatigue damage was greater than 1.0. The fatigue damage on the pile is illustrated on Figure 3.

Table 2 Partial Fatigue Damage.

Driving Depth (m)	Blows per meter	Stress Gab (MPa)	Fatigue Damage
7	26	9.9	$2.2 \times 10^{-8}$
8	28	14.7	$1.8 \times 10^{-5}$
9	24	14.7	$3.3 \times 10^{-5}$
10	32	14.7	$5.6 \times 10^{-5}$
11	29	18.5	$3.9 \times 10^{-3}$
12	35	18.5	$8.3 \times 10^{-3}$
13	41	18.5	$1.3 \times 10^{-2}$
14	47	18.5	$1.9 \times 10^{-2}$
15	108	21.8	1.3
16	131	21.7	2.6

The interval between the crushed zones is measured to approximated 0.30 m as expected the pile width divided by  $\sqrt{2}$ .

Figure 3. Fatigue Damage on the Pile

#### 4 RECOMMENDATIONS

Based upon the results from the driveability study the stresses in the pile can be assessed for different stroke values. With the given stroke and the stresses the number of blows can be calculated in order to get the fa-

tigue damage 1.0. In Figure 4 the total number of blows are given compared to the stroke. It can be seen that for the actual pile the stroke should be limited to 0.5 m in order to avoid fatigue damage in the actual concrete piles.

Figure 4. Total Number of Blows versus Stroke

In Figure 5 the results of the driveability study for stroke up to 1.0 m and for maximum stroke 0.5 m are given. If the stroke of the hammer had been limited to 0.5 m the piles could have been driven to target penetration without fatigue damage.

Figure 5. Expected driving Resistance for max. Stroke 1.0 m and Limit Stroke 0.5 m.

Generally it is recommended for concrete piles to limit the stroke of hammers to 0.5 or 0.6 m in order to avoid pile driving fatigue damage.
